In the last issue of *Forth Dimensions*, I presented a program that used the Bresenham algorithm to draw lines on a computer graphics display. Now I will build upon those definitions to create a program that draws pseudo-randomly generated fractal landscapes with height-based coloring (including a sea-level) and hidden-surface elimination.

**What's a Fractal?**

The word fractal is short for “fractional dimension,” and is used to describe various geometrical shapes that are not strictly one, two, or three-dimensional objects. Interestingly enough, most naturally occurring objects (such as coastlines) and natural phenomena (such as Brownian motion) are best described by fractal geometry.

To get a better feel for what a fractal is, consider the western coastline of the United States. From far away in space, the coastline looks more-or-less straight; that is, it looks like a one-dimensional line having a fractional dimension near 1. As an observer gets closer, the perceived length of the coastline and its fractional dimension increases as more details such as inlets and peninsulas become visible. In fact, with a very close look at an area like San Francisco Bay, the coastline becomes a two-dimensional object with a fractional dimension near 2.

**How To Draw Random Fractals**

To use the fractal concept to draw a landscape, let's first look at how a fractal can be used to draw a shape, starting from a line. We will look at a random fractal line, but of course there are other ways to draw fractal lines (see the recommended reading list).

First, consider the straight line segment shown in Figure One-a. We will take the midpoint of that line segment and pull it to one side, as shown in Figure One-b. Next, we will recursively take each midpoint of the resulting line segments and pull them randomly to one side or the other as shown in Figures One-c and One-d. As you can see, this process quickly results in a wandering line. For the most pleasing shape, the amount of "pull" applied is cut in half at each level of recursion, forming a smooth result.

In order to extend this concept to an area instead of a line, the "Landscape" program on screens 15-28 forms a two-dimensional array. Each cell in the array holds the height of a point above or below sea level. The word CALCULATE-SERVICE recursively breaks this array into smaller and smaller squares, using the addresses of the four corners of the array instead of four pairs of (X,Y) coordinates. SET-HEIGHTS sets the heights for the array cells at the midpoints of the sides of the current square and for the center of the current square, then breaks the square up into four sub-squares (see the diagram on screen 17 for a description of the nomenclature used by the subdividing algorithm). After the data array has a height associated with each point, the program uses the SEA-LEVEL word to reassign all negative heights to sea level.

After the heights are computed, the landscape is drawn on the screen. As each point of the array is drawn, it is assigned a color based on height and the number of colors available.

Screen-Drawing Tricks

I have used several tricks in "Landscape" to speed up the screen-drawing time. This drawing time would be prohibitively long if conventional, three-dimensional graphics techniques were used.

The most time-consuming part of many graphics drawing programs involves 3-D transformations, especially rotations. On the other hand, a top or side view of a fractal landscape would not be terribly exciting. I solved this speed-versus-prettiness dilemma using two techniques: a "sleazy" rotation to elevate the rear of the picture, and an

unconventional point-connection scheme to eliminate the need for spinning the picture.

A standard rotation of a landscape to elevate the rear of the picture involves using the equation:

\[
\text{NEWY} = \text{yvalue} \times \sin(\text{angle}) + \text{height} \times \cos(\text{angle})
\]

for each height data point in the landscape array. In order to eliminate the scaled integer or floating-point arithmetic involved, I chose my rotation angle to be 30 degrees and changed the \(\times \sin(\text{angle})\) term to a division by two. Then, to get rid of the cosine term, I decided to approximate \(\cos(30) = 0.866\) by 0.5 (division by two) and increased the original height value on line 7 of screen 28 to compensate. The elevation using this strategy is accomplished by \textsc{y-convert} on screen 19.

Even with the rear of the picture elevated, the result is pretty unexciting if points are connected by columns and rows. You would only see regularly spaced vertical lines with landscape profile lines wiggling horizontally across the screen. In order to fix this, lines 10 through 12 of screen 21 connect points in sideways “V” patterns to form a picture composed of diagonal lines instead of mostly horizontal and vertical lines. The lines are drawn and colored by columns of points, front to back.

It turns out that hidden-surface elimination, a major computational drain on many graphics programs, comes at almost no charge when using the drawing technique described above. Since points are drawn from front to back, lines 5 - 7 of screen 21 simply ensure that each new \(Y\) value for a point to be displayed is further up on the screen than any previous \(Y\) values for that column.

Running The Program

Simply type \textsc{landscape} from the Forth “OK” prompt. The program will draw a landscape and wait for a keystroke on a PC-compatible machine with a Color Graphics Adapter (CGA) display. If you change the constants on lines 2 - 3 of screen 18, redefine the coloring word on lines 9 - 14 of screen 20, and substitute (Continued on page 11.)
For Programming Professionals:
an expanding family of
compatible, high-performance,
Forth-83 Standard compilers
for microcomputers

For Development:
Interactive Forth-83 Interpreter/Compilers
• 16-bit and 32-bit implementations
• Full screen editor and assembler
• Uses standard operating system files
• 400 page manual written in plain English
• Options include software floating point, arithmetic
coprocessor support, symbolic debugger, native code
compilers, and graphics support

For Applications: Forth-83 Metacompiler
• Unique table-driven multi-pass Forth compiler
• Compiles compact ROMable or disk-based applications
• Excellent error handling
• Produces headerless code, compiles from intermediate
states, and performs conditional compilation
• Cross-compiles to 8080, 280, 8086, 68000, 6502, 8051,
8096, 1802, and 6303
• No license fee or royalty for compiled applications

For Speed: CForth Application Compiler
• Translates "high-level" Forth into in-line, optimized
machine code
• Can generate ROMable code
