Housekeeping

- Your goal today
 - understand how to guess your way through control flow and why it works so well
- Notices
 - Lab 2, status check this week, due next week
 - HW 3, due **Wed** 3/13 (Handout #8)
- Readings
 - P&H Ch 4

Branch Prediction 101: PC+4

t_4 t_5

In general as long as

- 1. prediction is always checked
- 2. correct target is fetched after a misprediction
- 3. wrong path instructions removed

****ANY**** predictor will work, including RNG, PC-4

18-447-S23-L10-S3, James C. Hoe, CMU/ECE/CALCM, ©2024

Prediction and Resolution in General

- "Trust (1), but verify (2)"
- When wrong, (3) clean up mistake and (4) update predictor to improve next guess

Tagged BTB (from last lecture)

Sum Up So Far

- Given current PC, speculate most likely next PC
- The easy part: target
 - same PC <u>always</u> same instruction
 - nextPC <u>always</u> PC+4 for non-control-flow inst
 - target of PC-offset control-flow <u>always</u> same

BTB from last slide works very well

- The not so easy part: taken?
 - branch decision is dynamically data dependent
 - so far, either 1. always-predict-not-taken (PC+4) or
 2. always-predict-taken (BTB)

Branch Direction Prediction

- Already 100% correct on non-control-flow inst
- Improve on always-predict-taken (70% correct)?
 - ~90% correct on backward branch (dynamic)
 - only ~50% correct on forward branch (dynamic)
 What pattern to leverage on forward branches?
- A given static branch instruction is likely to be biased in one direction (either taken or not taken)
 - 80~90% correct (forward+backward) if guessed to repeat the outcome last time
 - IPC = 1 / [1 + (0.20*0.15) * 2] = 0.94

"Adaptive" History-Based Prediction

Branch History State Machine

Predict same as last outcome

2-Bit Saturation Counter

2-Bit "Hysteresis" Counter

Change prediction after 2 consecutive mistakes

Per-Branch Counter-Based BP

- 2-bit counter can get >90% correct
 - IPC = 1 / [1 + (0.20*0.10) * 2] = 0.96
 - any "reasonable" 2-bit counter works
 - adding more bits to counter does not help much
- Major branch behaviors exploited
 - almost always repeat the same (>80%)
 - 1-bit and 2-bit counters equally effective
 - occasionally do the opposite once (5~10%)
 - 2 misprediction with a 1-bit counter
 - 1 misprediction with a 2-bit counter
- Need more elaborate predictors for other behaviors Is it worth the cost? Will it slow down the clock?

The cost of misprediction

- Misprediction penalty increases with
 - number of pipeline stages
 - width of superscalarity
 - number of nested predictions (fxn of BB size)
 - rewind cost

Multiple shots at better predictions

Beyond Local History: Path History

- Branch outcome may be correlated to other branches
- Equntott, SPEC92
- If B1 is not taken (i.e. aa==0@B3) and B2 is not taken (i.e. bb=0@B3) then B3 is certainly taken

How to capture this information?

Gshare Branch Prediction [McFarling]

18-447-S23-L10-S17, James C. Hoe, CMU/ECE/CALCM, ©2024

Return Address Stack

- A register-indirect jump can have different target
 - same target only if fxn called repeatedly from same call-site
 - but, function call and return behavior easily tracked by a last-in-first-out queue
- Return Address Stack
 - return address is pushed when a link instruction (i.e., JAL x1...) is executed
 - when encountering PC of a return instruction (i.e., JALR ...x1) predict nPC from top of stack and pop

What happens when the stack overflows? How do you know when to follow RAS vs BTB?

Alpha 21264 Tournament Predictor

- Make separate predictions using local history (per branch) and global history (correlating all branches) to capture different branch behaviors
- A meta-predictor decides which predictor to believe

Better than 97% correct

Superscalar Complications

- "Superscalar" processors need to fetch multiple instructions per cycle
- Consider 2-way superscalar fetch scenario
 (case 1) both instructions are not taken control-flow
 - nPC = PC + 8
 - (case 2) one inst is a <u>taken</u> control-flow inst
 - nPC = predicted target addr
 - note: both instructions could be control-flow; target is for younger of predicted taken
 - if 1st instruction is predicted taken, nullify 2nd
 instruction fetched

2-way Branch Predictor Sketch

Trace Caching

Intel P4 Trace Cache

- A 12K-uop trace cache in place of L1 I-cache
- 6-uop per trace block, can include branches
- Trace cache returns 3-uop per cycle
- IA-32 decoder can be simpler and slower <<<

Ways SW can Help

- Associate static branch "hints" with opcodes
 - taken vs. not-taken
 - whether to allocate entry in dynamic BP hardware
- Give SW and HW joint control of BP hardware
 - Intel Itanium BRP (branch prediction) instruction issued ahead of branch to preset BTB state
- TAR (Target Address Register, Itanium)
 - a small, fully-associative BTB
 - controlled entirely by BRP instructions
 - a hit in TAR overrides all other predictors

Relieves "urgency" by not wait to compute branch condition and target as last inst in basic block

Predicated Execution

- Intel Itanium example
 - predicate register file (64 by 1-bit)
 - each instruction has a predicate reg argument
 - instruction is NOP if predicate is false at runtime
- Converting control flow into dataflow

Interrupt Control Transfer

- Basic Part: an "unplanned" fxn call to a "third-party" routine; and later return control back to point of interruption
- Tricky Part: interrupted thread cannot anticipate/prepare for this control transfer
 - must be 100% transparent
 - not enough to impose all calleesave convention (return address??)
- **Puzzling Part:** why is there a hidden routine running invisibly?
